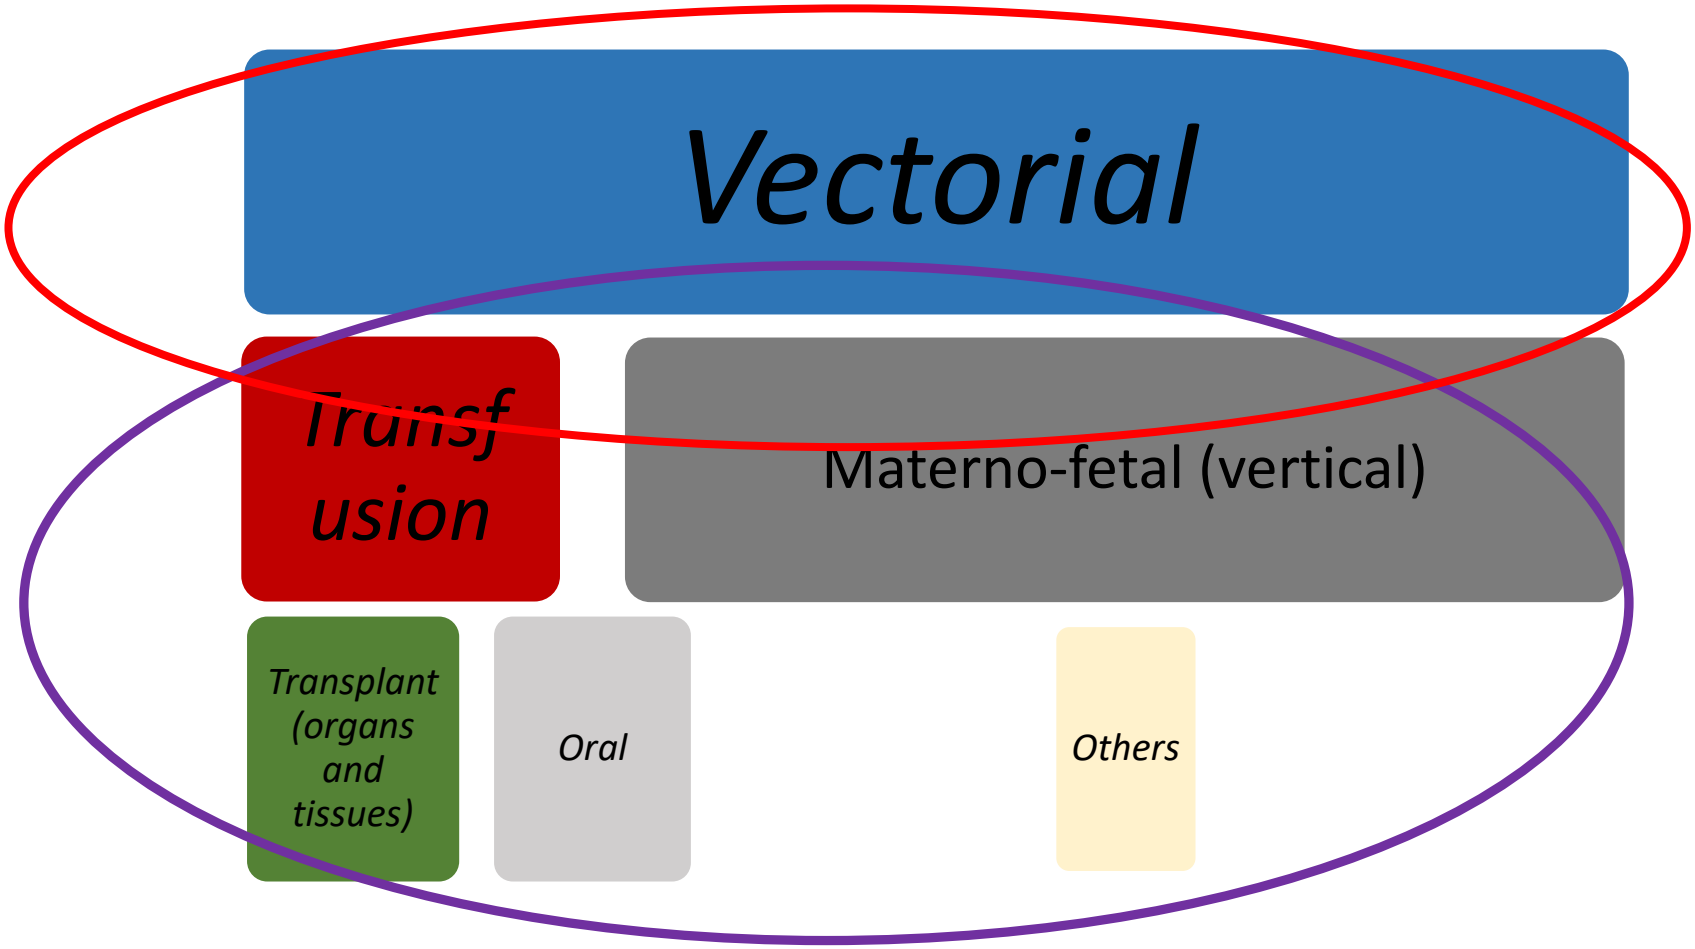
Chagas disease or American trypanosomiasis

Chagas disease is a zoonosis with a complex ecology* and cycle. Endemic exclusively in the American continent, it was discovered and fully described by the Brazilian doctor Carlos Chagas.

Its cause is the hemoflagellate protozoan *T. cruzi,* which is mainly transmitted to humans by the socalled kissing ugs of the family Triatominae.

*hundred of mammalian hosts, many triatomine vectors

Transmission ways



Transmission risk:

- **Contact with infected triatomine: 0,1%**
- **Single whole blood transfusion (500 ml): 12-20%**
- **Renal trnasplant from an infected donor: 35%**
- **Reactivation in course of immunesuppression: 30%**
- **Vertical: 0,1-12% (4,2% in non endemic countries)**

Chagas disease: oral transmission→ foods

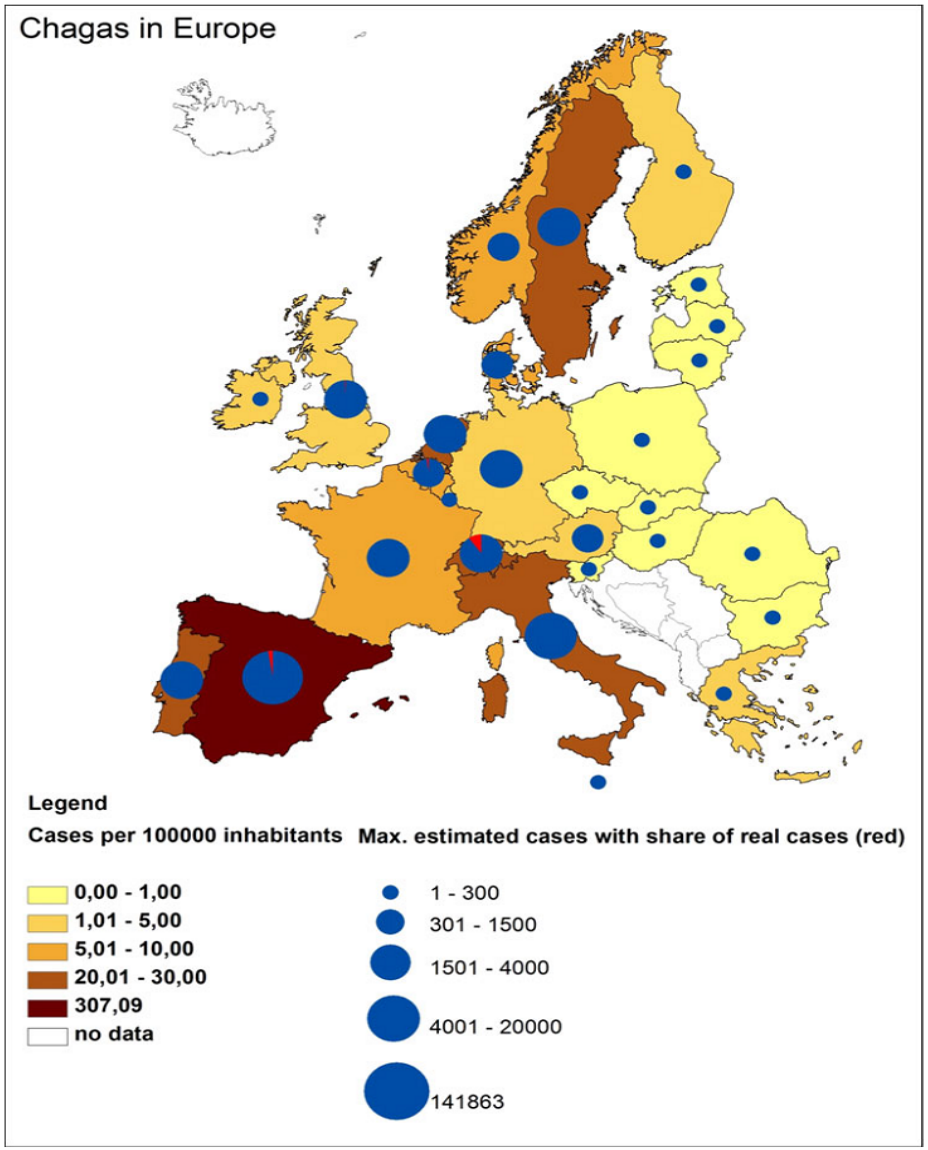
REVIEW

Epidemiology of Chagas disease in Europe: many calculations, little knowledge

Jörn Strasen · Tatjana Williams · Georg Ertl · Thomas Zoller · August Stich · Oliver Ritter

Received: 12 July 2013 / Accepted: 14 August 2013

Fig. 1 Incidence of Chagas disease from *light* to *dark* color, showing the biggest incidences in Spain, followed by Italy and Portugal and, surprisingly, Sweden, Switzerland, and the Netherlands. The maximum absolute number of cases is shown by *blue spots*. By far again Spain is most affected, again followed by Italy and again the Netherlands and then Germany and France. In the *red shares*, the portion of indentified patients is illustrated, showing visible shares only for Switzerland, Spain and Belgium [11] (Tables 2, 3, and 4)



Hotez PJ, Dumonteil E, Betancourt Cravioto M, Bottazzi ME, Tapia-Conyer R, et al. (2013) An Unfolding Tragedy of Chagas Disease in North America. PLoS Negl Trop Dis 7(10): e2300. doi:10.1371/journal.pntd.0002300 http://127.0.0.1:8081/plosntds/article?id=info:doi/10.1371/journal.pntd.0002300

Table 4. Pooled *T. cruzi* prevalence by country of origin in Latin American migrants from European countries.

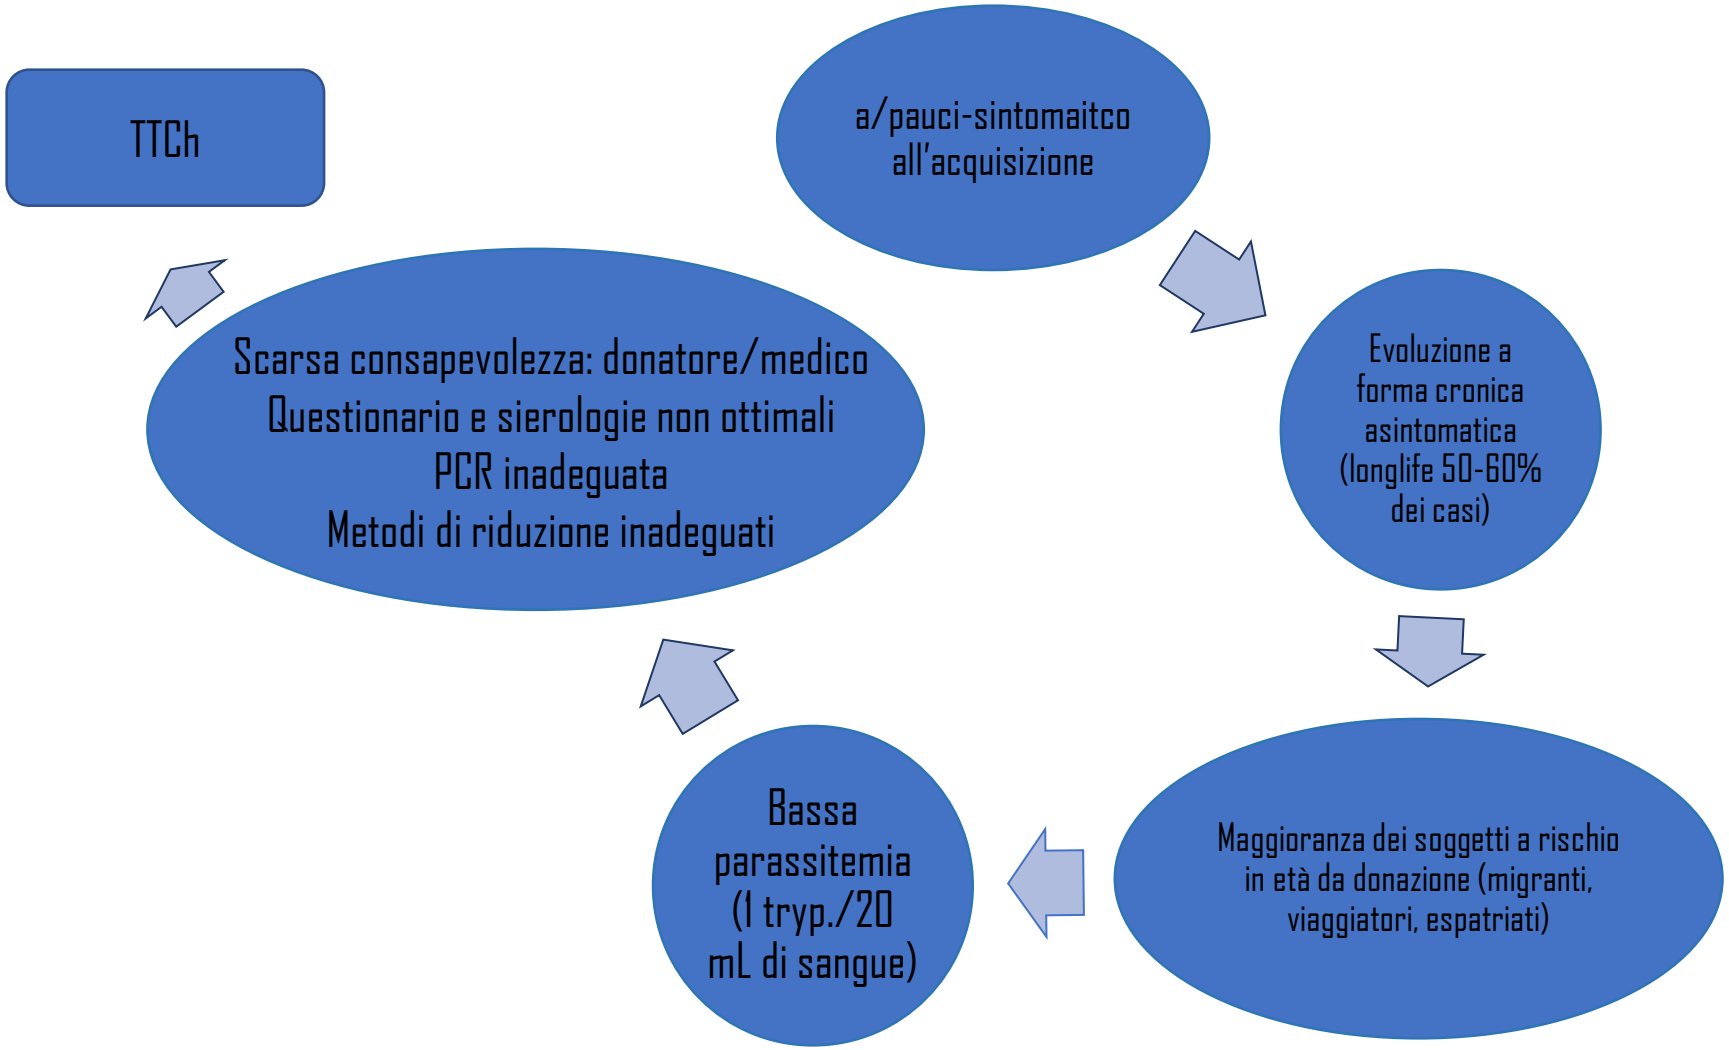
Chagas: «insidie trasfusionali»



Chagas disease and blood transfusion

- Firs case decribed in1952; then USA 80s, Spain 1992; **350** cases reported in the literature, at least 800 cases are estimated in the last decades...

Wendel S . Transfusion-transmitted Chagas' disease. Curr Opin Hematol 1998; **5**: 406-11.

Hernande z-Becerril N, Mejia AM, Ballinas-Verdugo MA, et al. Mem Inst Oswaldo Cruz 2005; **100**: 111-6.

Chagas disease and blood transfusion

- After the implementation of screening in LA: 1:200000 units is estimated infected; in non endemic countries about 1:30000;

- All blood components can transmit (***T.cruzi*** **survives 18 days at 4°C, 250 days at room temperature**); **PLT have the highest risk**

- Incubation time TTCh: 20-40 days, (8-120)

- 20% of TTCh is asymptomatic

Alcuni (15) casi di TTCh sono stati descritti in USA, Canada e Spagna, Messico. Tutti da trasfusione di PLT. Non efficacie la leucoriduzione (Benjamin et al. Transfusion 2012;52:1913-21.)

Perché in particolare le piastrine?

Cancino-Faure et al*. Hanno dimostrato ciò che l'esperienza aveva evidenziato e cioè **che le PLT sono l'emocomponente più a rischio per la trasmissione del Chagas**;

Nello studio (donatori PCR+ su sangue periferico → aferesi) le PLT erano al 100% positive alla PCR *T.cruzi*, mentre nel sangue periferico la carica parassitaria era 5X inferiore; plasma neg;

Le dimensioni (16-20 µm) di *T.cruzi* e il suo peso specifico stanno tra quelli delle PLT e dei globuli bianchi

Latinamerican migrants and blood transfusion?

Yves Jackson et al*, Plos NTD 2010 during a survey on Chagas disease among LA migrants living in Geneva, Switzerland, found that 18,5% of enrolled individuals are willing to donate or donated blood in Switzerland.

Chagas disease, a neglected tr
due to population movements i
to Latin America, threatens a wi
ple (travellers, migrants, blood or organ recipients, newborns, adoptees) also in non-endemic countries where it is generally underdiagnosed. In Italy, the available epidemiological data about Chagas disease have been very limited up to now, although the country is second in Europe only to Spain in the number of residents from Latin American. Among 867 at-risk subjects screened between 1998 and 2010, the Centre for Tropical Diseases in Negrar (Verona) and the Infectious and Tropical Diseases Unit, University of Florence found 4.2% patients with positive serology for Chagas disease (83.4% of them migrants, 13.8% adoptees). No cases of Chagas disease were identified in blood donors or HIV-positive patients of Latin American origin. Among 214 Latin American pregnant women, three were infected (resulting in abortion in one case). In 2005 a case of acute Chagas disease was recorded in an Italian traveller. Based on our observations, we believe that a wider assessment of the epidemiological situation is urgently required in our country and public health measures preventing transmission and improving access to diagnosis and treatment should be implemented.

Su 28 donatori testati, 0% di prevalenza…

Jnited States to Mexico and Central
a. In endemic countries it is respon-
est estimated burden of neglected tropical diseases, affecting 8 to 10 million people [1]. As a consequence of migration flows, the disease has been recorded also in non-endemic countries and is becoming a global health problem [2]. In Europe, about 59,000-108,000 cases of Chagas disease are estimated [3] . Italy has a large number of Latin American resident migrants, second in Europe only to Spain, as a result of various migratory waves to Argentina, Brazil, Chile, Uruguay and Venezuela through the last 200 years, until the direction of migration reversed in the 1970s [3].

The majority of Latin American migrants reached Italy in the past ten years, with a growing trend [4] . Migrants from different countries tend to have a patchy distribution in Italian Regions, with a major concentration in the north and in Rome. For instance most Bolivians live in Bergamo Province, Lombardy, Ecuadorians in Liguria Region and Peruvians in big cities such as Milan, Florence and Rome [4].

This new epidemiological scenario prompted the Centre for Tropical Diseases in Negrar (CTDN) and the Infectious and Tropical Diseases Unit, University of

Background. Chagas disease is a parasitic disease due to *Trypanosoma cruzi*, endemic in Central and Southern America, where the protozoon infects about 8-10 million people. In rural areas the infection is acquired mostly through reduviidae insect vectors, whereas in urban ones it is acquired mainly through the transfusion of blood products, vertical transmission and organ transplantation. The important migratory flows of the last decades have focused attention on possible *T. cruzi* transmission by transfusion also in non-endemic countries, and platelets have been recognised as the main origin of infection for recipients from serologically-positive Latino-American donors.

Materials and methods. In order to avoid the occurrence of transfusion-related cases, in 2010 systematic screening for anti-*T. cruzi* antibodies was started at the Umberto I Polyclinic in Rome, controlling blood donors born and/or coming from Latin-American countries in which the disease is endemic. The aim of this paper is to report the preliminary results achieved since the introduction of this screening.

Results. Anti-*T. cruzi* antibodies have been detected to date in 3.9% out of the 128 people examined. A seropositive subject also proved positive by polymerase chain reaction analysis and showed very light parasitaemia.

Su 128 donatori testati, 3,9% di prevalenza…un caso parassitemico

WISCENTD

Introduction

The importance of data

Neglected tropical diseases (NTDs) disfigure and disable, leading to stigmatization and social discrimination. Severe complications and death can result if treatment is not provided early and adequately. This group of diseases largely affects low-income, politically marginalized people living in rural and periurban areas with low visibility and little political voice and with limited access to health care. NTDs are mainly focal and present in remote areas. However, they can be controlled, prevented and possibly eliminated or even eradicated with proven interventions. Strong surveillance systems should be in place in order to understand the burden of NTDs, to describe their geographical distribution and to identify populations at risk in order to best target control interventions in this resource constrained context and take evidence-based decisions.

Malaria: scenarios

- Individuals who never had malaria (exemple, a traveller) → no immunity
- Like a newborn when maternal antibodies are lost (>six months)
- Like a child born from migrant woman who returns to the country of origin of the family
- Like the adult migrant who comes back to his/her country afterm many years of permanence on malaria non-endemic areas (specific immunity is lost)

FULL SUSCEPTIBILITY TO MALARIA
INCLUDED SEVERE FORMS

Malaria: scenarios

- On the other side an individual who has had numerous malaria attacks

LESS EVIDENT SYMPTOMS

NO SEVERITY

TROPICAL SPLENOMEGALY =

(HYPERREACTIVE MALARIAL SPLENOMEGALY)

Malaria: transfusion transmitted malaria (TTM)

- Casi di trasmissione trasfusionale (TTM) noti dal 1911[1]
- TTM possibile con globuli rossi concentrati (globuli rossi conservati a 4°C fino a circa 20 gg), piastrine, leucociti, plasma fresco congelato[2]
- Bastano 10 plasmodi per trasmettere la malattia da zanzara
- TTM rara in Paesi non endemici[2]
- Italia: 0-2 casi per milione di donazioni[2]

[1]Woolsey G. Ann Surg 1911
[2]Grande R. Blood Transfus 2011

Malaria da trasfusione di sangue/emocomponenti (TTM)

- Delle cinque specie di *Plasmodium*, il *falciparum* è il più pericoloso in quanto comporta un 10% di mortalità in caso di TTM[1]

[1]Mungai M et al. *N Engl J Med* 2001; **344**:1973–1978

Malaria: TTM

- As a result of the asymptomatic persistence of parasites, transmission of *P. malariae* has been documented as long as 53 years [22], *P. vivax* 27 years [23] and *P. falciparum* 13 years [23] after the last exposure

[22] Gauzzi M, Grazan S: *Trop Dis Bull* 1964; **61**:11–12

[23] Besson P, et al.: *Rev Fr Transfus Immunohematol* 1976; **19**:369–373

Table 1. Reported cases of transfusion transmitted malaria (TTM) in Italy.

Country#	Year	Donor gender & age	Donor origin & last exposure	Recipient gender & age	Recipient incubation (Delayed diagnosis)	Recipient outcome	Blood § component transfused	*Plasmodium* species	Diagnosis Method Recipient (Donor)	Reference
Italy										
Liguria	1963	N/A	N/A	M premature	28-40 days	recovery	WB	*P. malariae*	LM	Sansone & Centa 1967
Liguria	1963	N/A	N/A	F 8 yrs	1-13 days	recovery	WB	*P. vivax*	LM	Sansone & Centa 1967
Liguria	1964	N/A	N/A	F 6 yrs	multiple transfusions (4 months)	recovery	WB	*P. vivax*	LM	Sansone & Centa 1967
Sicily	2005	M	Philippine	F 35 yrs	multiple transfusions (4 months)	recovery	WB	*P. malariae*	LM	Neri et al., 2008
Veneto	2008	N/A	N/A	F 29 yrs Morocco	multiple transfusions (2 weeks)	recovery	RBCs	*P. vivax*	LM	Tagariello et al., 2014

only non-endemic areas of the country if malaria endemic were included; N/A: data not available.

§ WB= whole blood, RBCs= red blood cells, PLTs= platelets, FFP= fresh frozen plasma.

LM: light microscopy; ELISA: enzyme-linked immunosorbent assay; IFAT: indirect immunofluorescent antibody test; PCR: polymerase chain reaction.

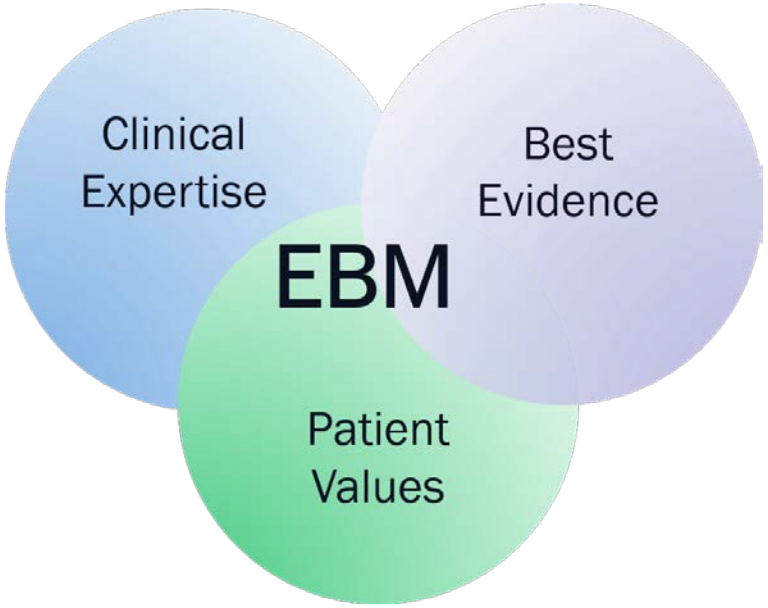
Quindi perché passare ad una valutazione non solo clinico-anamnestica di selezione del donatore come fatto nel 2015?



Some countries only apply selective epidemiological questionnaires (e.g. Canada, USA), while others reinforce their selection measures with immunological tests and/or molecular techniques (e.g. Australia, France, England, Italy, Spain and Portugal

Table 3
Documented transfusi

Management of TTM at the Australian Red Cross Blood Service (Blood Service) combines the identification of 'at-risk' donors', targeted antibody screening [malaria antibody enzyme-linked immunoassay (EIA)] and, if reactive, exclusion from the manufacture of fresh blood components.
The estimated residual risk of TTM with this strategy is low (<1 in 3,3 million)

Malaria: TTM

- Grande et al. hanno screenato (EIA Ab totali e Ag pan, Pf e pv) 412 donatori a rischio di malaria (16,8% italiani viaggiatori):

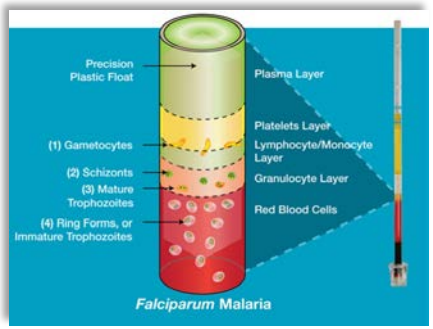
- 91,3% negativi; 8,7% positivi EIA, non Ag: quali vantaggi?

→ Possibile riammissione a 4 mesi nel 90% dei donatori, non affidamento alla sola clinica

Grande R. Blood Transfus 2011

Malaria: diagnosi

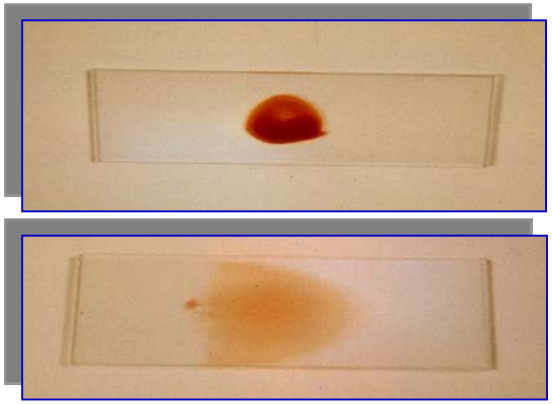
- QBC®



QBC: 1p/µL

- Se p<10/µL dx 50% times earlier than GS

- GS/SS



GS: 1-20 p/µL

SS: 200p/µL

- Antigen malarial test

(HRPII → P.falc, pLDH → 4 specie)

Bassa sensibilità se <100p/µL

Diagnosi di malaria: tecniche molecolari

- Sono disponibili tecniche per infezione mista e diagnosi di specie
- Elevata sensibilità:

- PCR: 3-5 p/µL (parassitemia 0,00006%)
- LAMP: 2 p/µL (parassitemia 0,00004%)

*Pv*AMA1	2.6 (0.4–∞)	2.8 (0.4–∞)	5.7 (0.8–∞)	4.0 (0.5–∞)

Values represent the estimated mean antibody response half-life in years with the 95% reference range. The predicted mean half-life was determined from the mixed-effects model with covariates set to the mean. The 95% reference ranges were derived from the estimate and between-woman standard deviation of the slope of the linear mixed-effects model. Multigravida had longer antibody half-lives compared to primigravida for VAR2CSA-DBL5 (64.8 [0.2–∞] compared to 36.0 [0.1–∞]).

Malaria antibody persistence correlates with duration of exposure

H. M. Faddy,[1] C. R. Seed,[2] M. J. Faddy,[3] R. L. Flower[1] & R. J. Harley[4]

Faddy et al. studied a population of blood donors and concluded that antibodies anti-Plasmodium spp. may persist in the bloodstream up to 19.6 months after the last exposure.

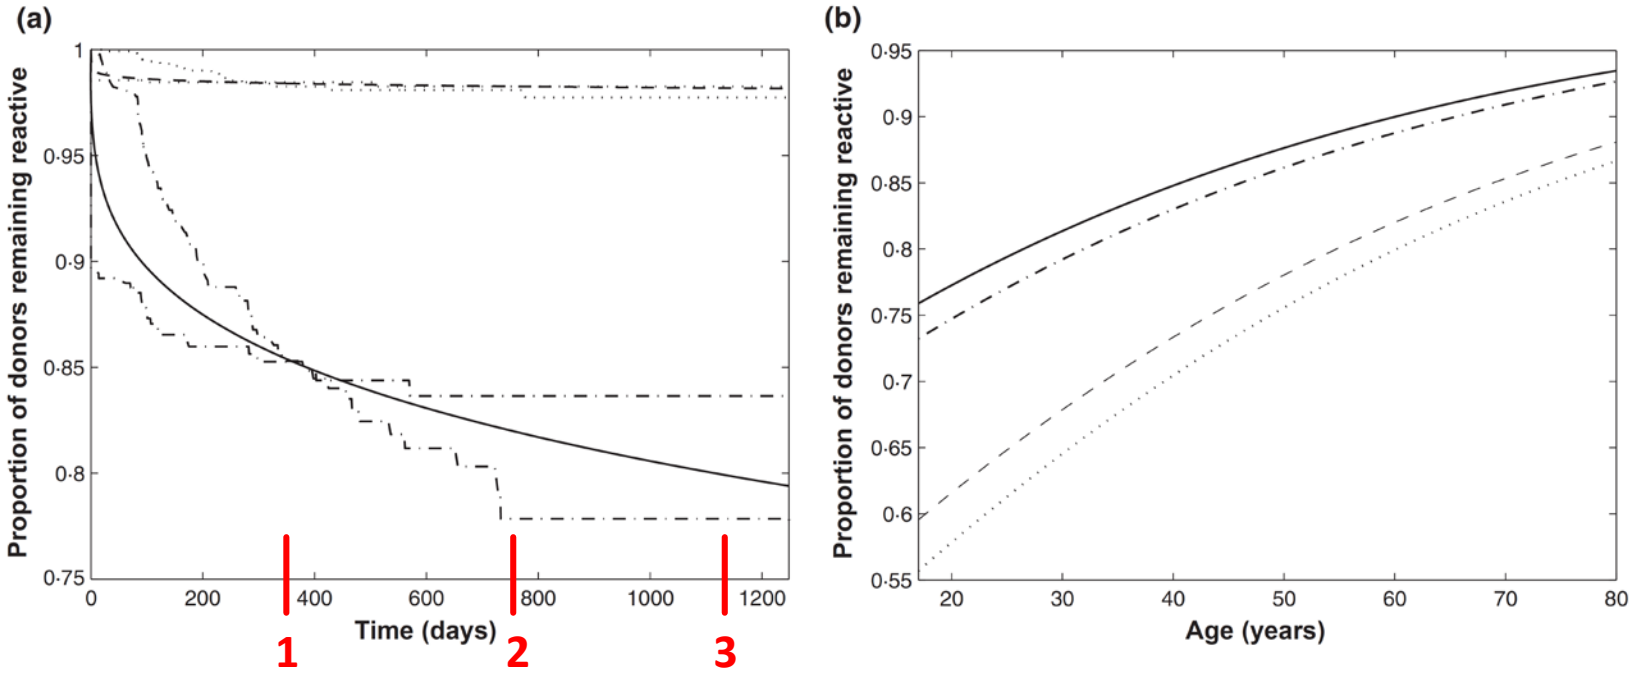

Fig. 3 Malaria-specific antibody survival modelling. Proportion of donors remaining reactive as a function of time; Kaplan–Meier extremes (-.-.-) and Weibull estimate (___) for 'Visitors'; and Kaplan–Meier extremes (….) and Weibull estimate (- -) for 'Residents' (a). Proportion of 'Visitors' remaining reactive as a function of age; Weibull estimates at 2 years for males (___) and females (- -) and at 3 years for males (-.-.-) and females (.....) (b).

Table 1 Proportion of donors predicted to test non-reactive

Time since first reactive EIA (years)	Proportion of 'Visitors' predicted to test non-reactive (%: 95% CI)	Proportion of 'Residents' predicted to test non-reactive (%: 95% CI)
1	15 (12–18)	2 (1–2)
2	18 (14–22)	2 (1–3)
3	20 (15–25)	2 (1–3)
4	21 (16–28)	2 (1–3)
5	23 (17–30)	2 (1–3)

Gli Ab anti-malaria sono utili, persistono a lungo (> negli autoctoni), ma ciò significa che quel donatore è parassitemico?

Quale test immunologico però?

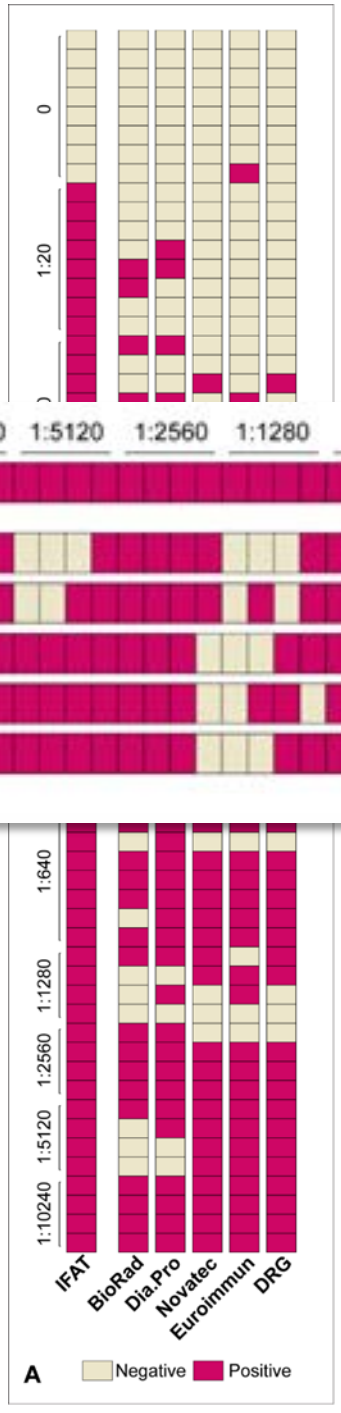
Mangano et al, 2018

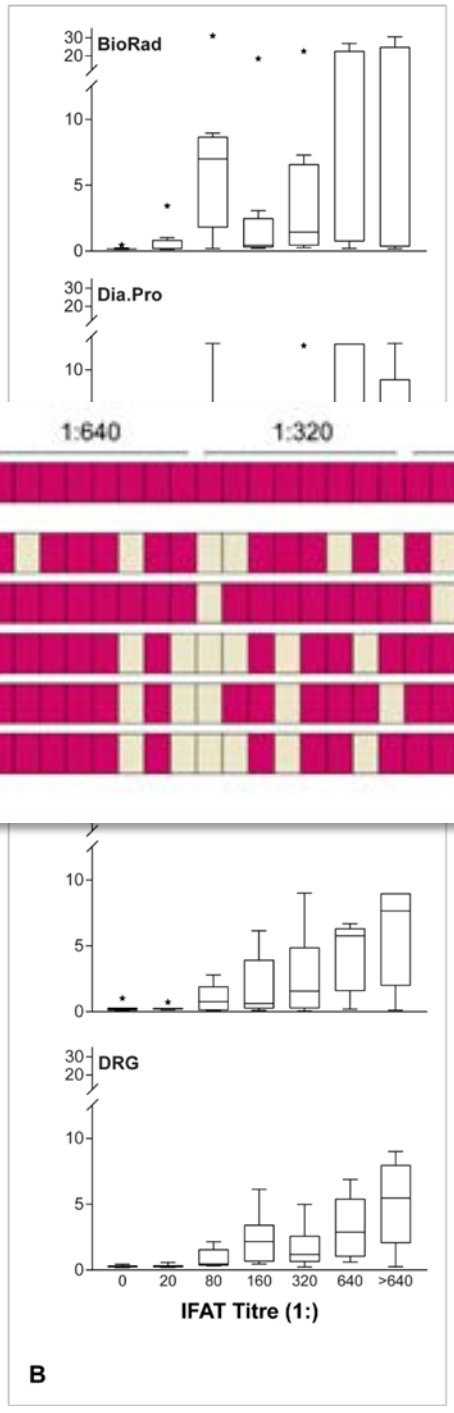
- **Retrospective** study using archived serum samples from subjects recruited in two Italian (Pisa, Negrar).

- In the absence of a gold standard for malaria serology, the aim of this work was to evaluate **five commercial ELISA kits**, in comparison to IFAT assay, and to determine their accuracy and agreement.

- Serum samples (N=64) from **malaria patients** or from subjects with **malaria history**, malaria naive patients with other parasitic infections (N=15), malaria naïve blood donors (N=8) and malaria exposed candidate blood donors (N=36) were tested.

- The specificity of all ELISA kits was 100%, while **sensitivity ranged between 53% - 64%** when compared to IFAT on malaria patients samples.
- When tested on candidate blood donors' samples, ELISA kits showed **highly variable agreement** (42% - 94%) raising the possibility that the same individual could be excluded from donation depending on the test in use by the transfusion centre.





Pair of ELISA kits	Concordance	Cohen's *k*
BioRad *vs.* Dia.Pro	95%	0.89
BioRad *vs.* DRG	78%	0.53
BioRad *vs.* Euroimmun	91%	0.8
BioRad *vs.* Novatec	55%	0.2
Dia.Pro *vs.* DRG	80%	0.57
Dia.Pro *vs.* Euroimmun	91%	0.8
Dia.Pro *vs.* Novatec	51%	0.17
DRG *vs.* Euroimmun	77%	0.49
DRG *vs.* Novatec	57%	0.21
Euroimmun *vs.* Novatec	58%	0.24

C

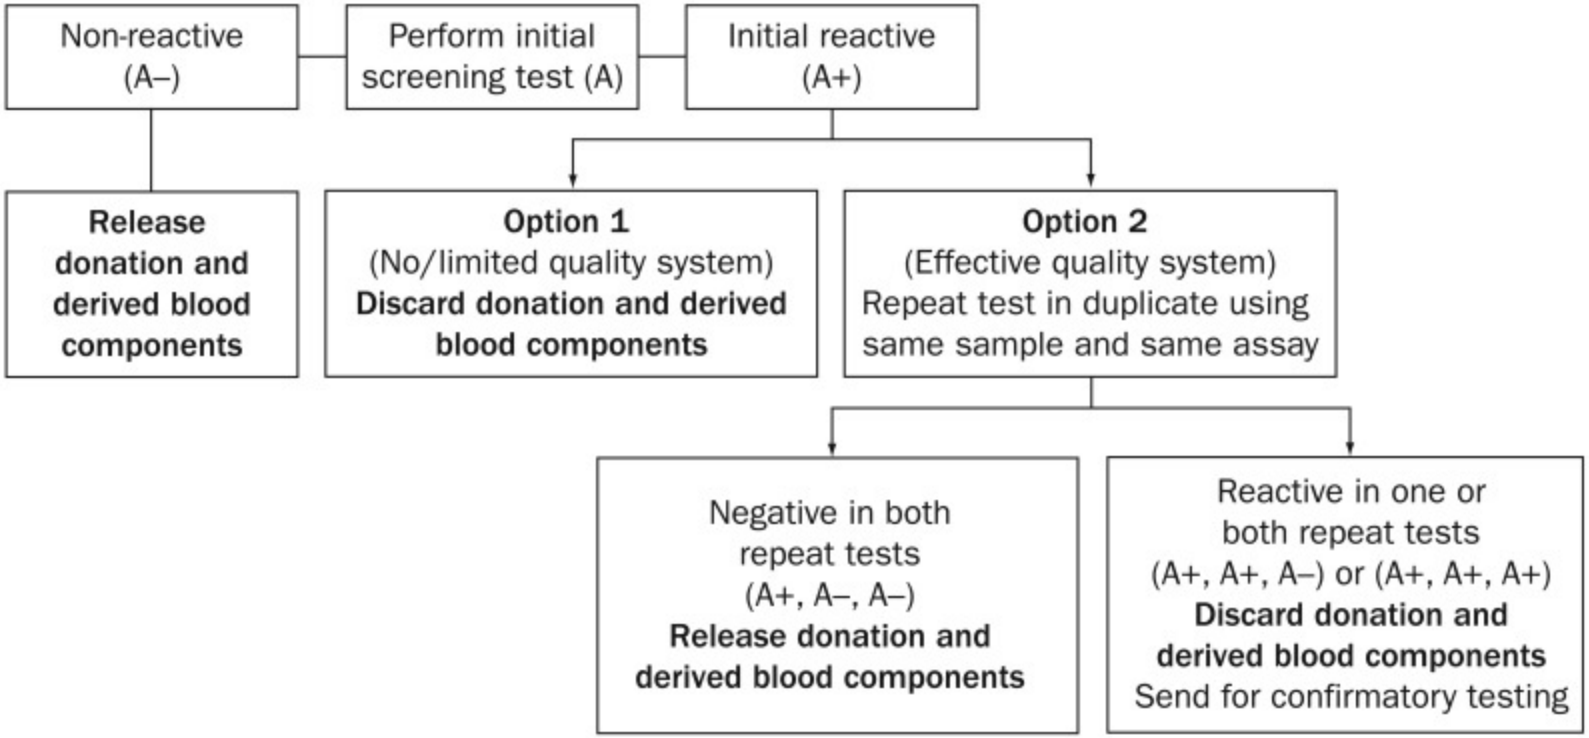
negative with all kits. Contrasting results were instead obtained for 27 samples (48%). **B)** Distribution of ELISA indexes according to IFAT titre (Tukey's boxplot). For Malaria ELISA, Anti-Plasmodium ELISA and NovaLisaTM malaria kits, a trend towards an increased ELISA index at higher IFAT titres was observed. However, for all kits, it was not possible to assign a given IFAT titre to a sample based on the ELISA index. **C)** Agreement of the results obtained with the ELISA kits on candidate blood donor samples (n=43). The concordance ranged from 51% (Cohen's *k*=0.17) for the comparison Malaria Ab *vs.* NovaLisaTM malaria, to 95% (Cohen's *k*=0.89) for the comparison Malaria EIA Test *vs.* Malaria Ab.

Protocollo di gestione (in discussione)

Cosa fare del donatore positivo EIA/IFAT per malaria?

Vari scenari:

- falso+ → da dimostrare
- Pz parassitemico → da trattare
- Pz con splenomegalia iper-reattiva malarica → da trattare



A = Assay
A+ = Reactive result in A
A– = Non-reactive result in A

Protocollo di gestione (in discussione)

Cosa fare del donatore positivo EIA/IFAT per malaria?

- Ripetere in doppio su stesso prelievo la sierologia per malaria (stesso test)
- Se uno dei due test è positivo, procedere a invio a centro di referenza per test di conferma dove:
- il paziente viene sottoposto a:
- Test sierologici (2 diversi, uno solo?)
- Emoc+formula, IgM totali, PCR (o LAMP) per malaria e antigenemia (meglio) oppure QBC/GS e antigenemia
- Inoltre a valutazione clinica per eventuale splenomegalia o pregressa storia di malaria da vivax (nel qual caso primachina?)
